Department of Electrical and Computer Engineering University of Waterloo

November 14, 2015

ECE 155 Winter 2016 1/29

Objective

Goal: a brief introduction to multithreading

ECE 155 Winter 2016 2/29

About Multithreading

First definition: a Process.

Process has three main components:
An executable program,
Data created/needed by the program, and
Execution context of the program

A process has at least one Thread.

ECE 155 Winter 2016 3/2

About Multithreading

Thread: A short form of Thread of Execution.

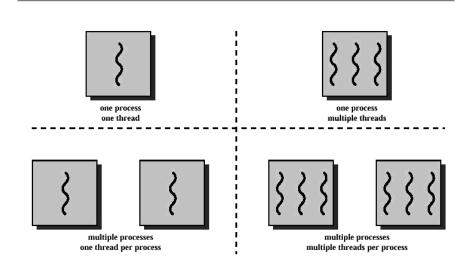

A sequence of executable commands that can be scheduled to run on the CPU.

A multithreaded program uses more than one thread at least some of the time.

Threads may be created and destroyed dynamically.

ECE 155 Winter 2016 4/29

Processes and Threads

ECE 155 Winter 2016 5/29

Thread States

Conceptually, a thread can be in one of three states:

- **■** Executing
- Ready
- Blocked

ECE 155 Winter 2016 6/29

About Multithreading

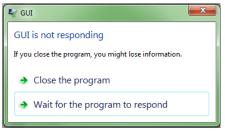

Very few programs written today are single threaded.

It is typical to separate UI from processing.

Example: File Transfer (FTP) program.

ECE 155 Winter 2016 7/2

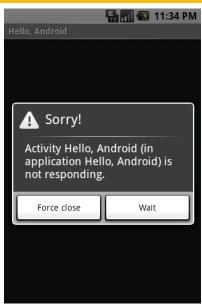

Not Responding

(From StackOverflow.com)

ECE 155 Winter 2016 8/29

Not Responding

(From linuxtopia.org)

Multithreading: FTP

Solution? Multithreading

When an upload is ready to start, a new thread is created.

Thread runs in the background.

UI Thread does not wait for the upload.

Android official guide says to use this.

ECE 155 Winter 2016 10/29

Inter-Process Communication

In most modern OSes, each process runs as if it's in its own world.

If this was not the case, processes could read memory of other processes!

Can still happen in embedded systems.

ECE 155 Winter 2016 11/29

Inter-Process Communication

Because of the "walls" between processes, communication is hard.

Alternative: communicate between multiple threads!

No enforcement of rules by the OS between threads.

ECE 155 Winter 2016 12/29

Inter-Process Communication

Alternative: Inter-Process Communication (IPC)

Used for data sharing, message passing, function calls.

Can be set up with files, shared memory, etc.

ECE 155 Winter 2016 13/29

Android IPC

Intents: used to ask another process to do something.

Explicit: Specify what process should handle the Intent.

Implicit: Ask OS to find programs that can handle the Intent.

If there is more than one, user gets a popup asking to choose.

Example: YouTube link can open in Browser or YouTube App.

ECE 155 Winter 2016 14/29

Android IPC

Intent is one way, but there is an alternative.

Binder: client-server model for comunication.

Details of the Binder are beyond the scope of this course.

ECE 155 Winter 2016 15/29

Processes vs. Threads

Threads ware faster to create and destroy than processes.

Less time to switch between threds in the same process.

Threads within the same process share memory and files. Can communicate easily.

ECE 155 Winter 2016 16/29

Processes vs. Threads

No protection between threads in the same process.

If any thread encounters an error, whole process will be halted; Independent processes can keep going if a related one stops.

ECE 155 Winter 2016 17/29

Multithreading: Execution

Assume a computer with 1 processor; 1 thread at a time

Still support multiple threads.

Time division: task switching.

Picture 3 threads.

User perception: threads executing in parallel

ECE 155 Winter 2016 18/29

Multithreading: Execution

Now: desktops, laptops, cell phones: multicore processors.

Multicore = multiple threads executing at once.

Time slicing still occurs if needed.

ECE 155 Winter 2016 19/29

Multithreading

Two kinds of multithreading: Co-operative and Pre-emptive

ECE 155 Winter 2016 20/29

Co-operative Multithreading

Used to be fairly common - even in Mac OS 9.

Threads yield the CPU.

Problem: greedy threads (never yield).

ECE 155 Winter 2016 21/29

Pre-Emptive Multithreading

Solution: let the OS decide when thread switch.

Every thread acts as if it's the only one.

No need to decide when is a good time to yield.

OS forces a thread switch when it is time.

ECE 155 Winter 2016 22/2^t

Pre-Emptive vs Co-operative

Usually you will see Pre-Emptive.

Embedded systems might not manage threads; might have to use co-operative.

Co-operative an be more efficient if everyone plays nicely.

However, one rogue thread can wreck it for everyone.

ECE 155 Winter 2016 23/29

Parallelism

Multiple threads at the same time = tasks completed faster?

ECE 155 Winter 2016 24/29

Parallelism

Depends on the nature of the task!

Fully paralellized: 2 \times Threads = 2 \times Speed

Partially paralellized: 2 \times Threads = (1 < n < 2) \times Speed

Cannot be paralellized: 2 \times Threads = 1 \times Speed

ECE 155 Winter 2016 25/2^t

Multithreading Bugs

Challenging to convert single threaded code to multithreaded.

Multithreaded programs are prone to new types of bugs.

Multithreaded bugs will come up later in the course, but we'll take time for a short preview.

ECE 155 Winter 2016 26/29

Debugging Parallel Programming

Let's imagine we have an instance of an object Location that has two co-ordinates, x and y.

```
location.setX(5); location.setX(10);
location.setY(7); location.setY(0);
```

ECE 155 Winter 2016 27/29

Location Example

Even if each method is atomic, we cannot guarantee an order.

Consider this order:

- 1 Set x to 5
- 2 Set x to 10
- 3 Set y to 0
- 4 Set y to 7

Result: (10, 7) - Inconsistent!

We'll see how to solve this when we get to debugging.

ECE 155 Winter 2016 28/29

Example: RaceCondition

Now we'll examine in Eclipse some code examples where we have a race condition.

(See the code examples folder in Learn for the source.)
